Errors

Capture all errors and group them according to user action to understand root cause.

AppPulse Mobile automatically captures the HTTP requests that failed, and also supplies an API enabling you to report things that went wrong in your code. Using semantic analysis, it identifies error messages that appeared in the user's UI. With that, you can easily find which user actions failed to perform, what the reason was for the failure (client code or network call), and identify the message your users may have seen.
